## A Battering Ram?

All evidence suggests that Pachycephalosaur skulls were built to withstand extreme forces

- 9 inches of solid bone
- Bone organized in a radial arrangement- structural support
- Articulation btw back of skull and vertebrae oriented to transfer forces linearly
- Articulation btw back of skull and vertebral column built to withstand sideways forces
- Vertebral column has tongue and groove articulations
- Spinal column is an S-shaped shock absorber

#### BUT

There is no 'locking' mechanism on skull to keep battering heads aligned Some Pachycephalosaurs have imprinted blood vessels on dome These factors suggests that headbutting may not be likely

## Intraspecies Competition (typically male-male)

Females are typically choosey Why? Because they have more to loose

Common rule in biology: Females are expensive to lose, males are cheap (e.g. deer hunting) Females choose the male most likely to provide the most successful offspring

Males compete with each other for access to female vs. female chooses the strongest male

Choosey females // Strong males have more offspring => SEXUAL selection Many ways to do this...

But: In general, maximize competition and minimize accidental deaths (= no fitness)

### Head butting Pachycephalosaurs

Bone structure was probably strong enough to withstand collision Convex nature would favor glancing blows Instead, dome and spines seem better suited for "flank butting"

![](_page_10_Picture_2.jpeg)

![](_page_10_Picture_3.jpeg)

![](_page_10_Picture_4.jpeg)

So... if head butting is the result of male-male competition, what should we expect to find?

Sexual dimorphism...

if males are primarily using their domes to headbutt, male domes will be under strong selective forces, while female domes will not.

### Psittacosaurus SKIN

Preserved skin from a China specimen Most of the body covered in large, irregular scales Hollow tubular bristles arranged down the tail No evidence that these structures are related to Saurischian feathers but jury is still out Possibly convergently evolved feather-like structures Communication? Display? Very cool.

#### **Basal Neoceratopsian**

Known from North-Central China; found in <u>Early Cretaceous</u> rocks

Hallmarks of more derived Neoceratopsians:

- Emphasized boney frill
- Larger head:body size ratio
- 3 fused vertebrae to support large head
- Upwardly hooked lower beak
- All Neoceratopsians (except most basal) => quadrupedal
