

Life History

- Record of events relating to
 - growth
 - development
 - reproduction
 - survival

Characteristics that define life history

- Age and size @ sexual maturity
- Amount & timing of reproduction
- Survival and mortality rates

asexual
sexual

Life history varies within & among species

(See other diets)

individuality

genetic variation or environmental conditions

Life history strategies: timing/nature of events

How does the organism allocate time/energy btw
(divide)

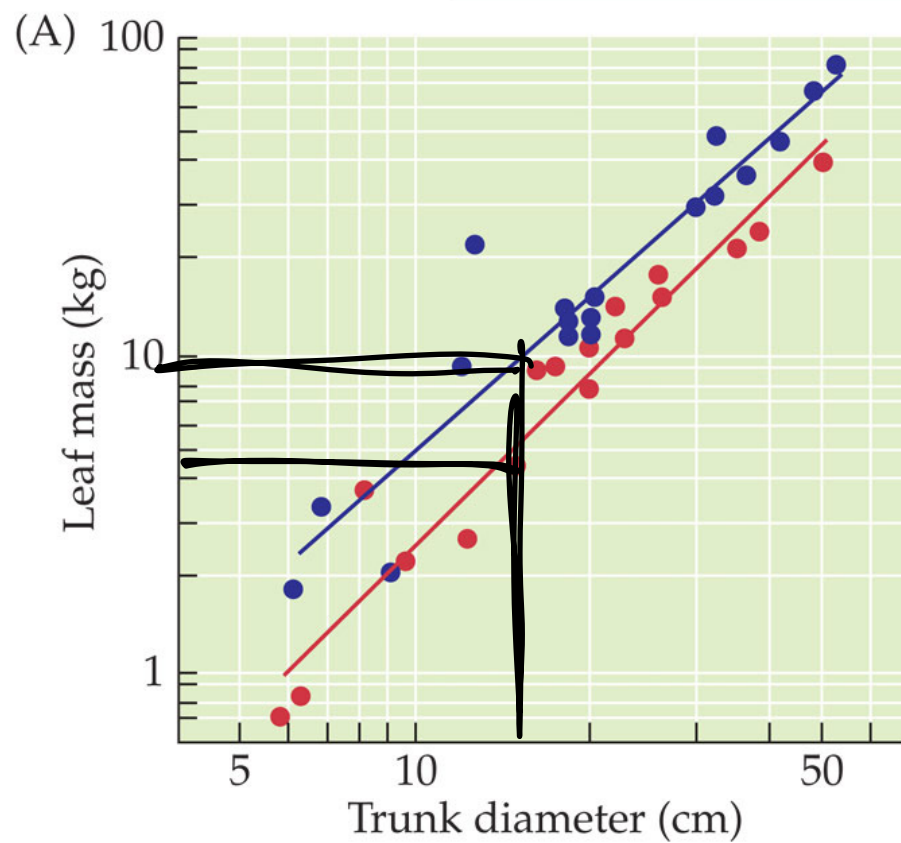

{ somatic growth
and maintenance
reproduction
survival

Maximizing relative fitness by adjusting life history via natural selection

● Cool, moist climate
● Desert climate

Phenotypic plasticity: one genotype produces different phenotypes under different environmental conditions

- ~~and~~ continuous

(A) Omnivore morph

(B) Carnivore morph

Omnivores feed on the pond bottom on detritus

ECOLOGY 3e, Figure 7.5

- grow slowly
- ↑ body condition

Carnivores feed in the water column on fairy shrimp

Ephemeral ponds (dry up)

- grow quickly

Asexual: simple cell division

(prokaryotes and many protists)

Sexual: Costs

- $\frac{1}{2}$ genome transmitted

- It takes 2 growth rate of populations is much lower

- recombination

⊕ introduces variation

C

Different forms of **isogamy**:

A) isogamy of motile cells, B) isogamy of non-motile cells, C) conjugation.

♀

♂

A

B

C

Different forms of **anisogamy**:

A) anisogamy of motile cells, B) oogamy (egg cell and sperm cell), C) anisogamy of non-motile cells (egg cell and spermatia).

Large expensive eggs

Small cheap sperm

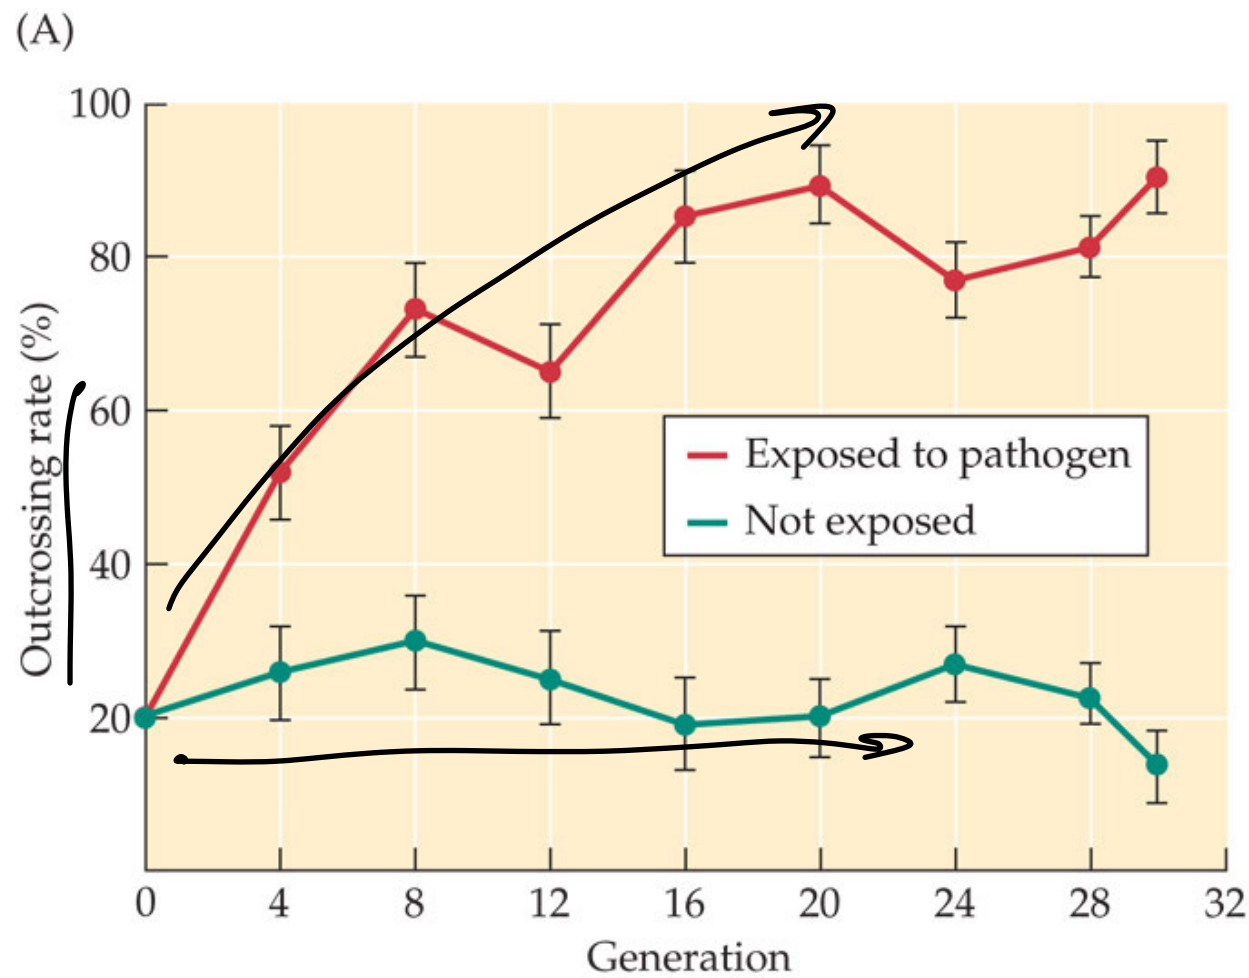

Each sex optimized to maximize its reproductive potential

- ♀ are the limiting factor bc they birth and often rear offspring

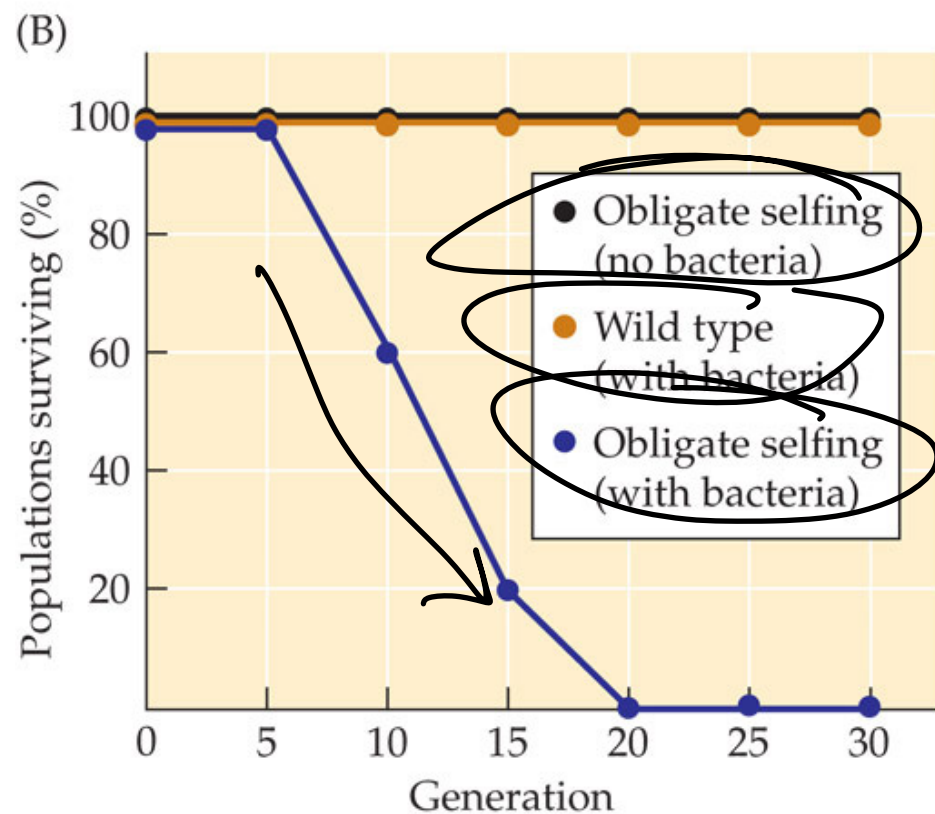

- ♂ are cheap

The cost of sex
i.e. the cost of males

C. elegans ♂ or hermaphrodites
 - Hermaphrodites can reproduce by selfing OR mating w/ ♂
 - genetic manipulations result in obligate < outcrossers vs. wild type

(+) bacterial pathogen

↑ genetic variation is key to living w/ pathogens

Some organisms have complex life cycles
(plants, fungi, algae, protists)

- Alternation of generations [Haploid phase, Diploid phase]
i.e. Multicellular diploid sporophytes

Wasps...

BBC

BBC

Number of reproductive bouts

Semelparous - reproduce 1X
- annual plants

- Some Pacific salmon

- rare in vertebrates apart from bony fish

Iteroparous - spp. reproduce multiple times
- birds, reptiles, mammals

[r-Selected
(many offspring)
Invest little energy
in each]

[K-selected
(few offspring)
Invest a lot of energy
in each]

Φ = Lifetime Reproductive value of an individual

\sim future reproductive success

- Maximized under mass selection

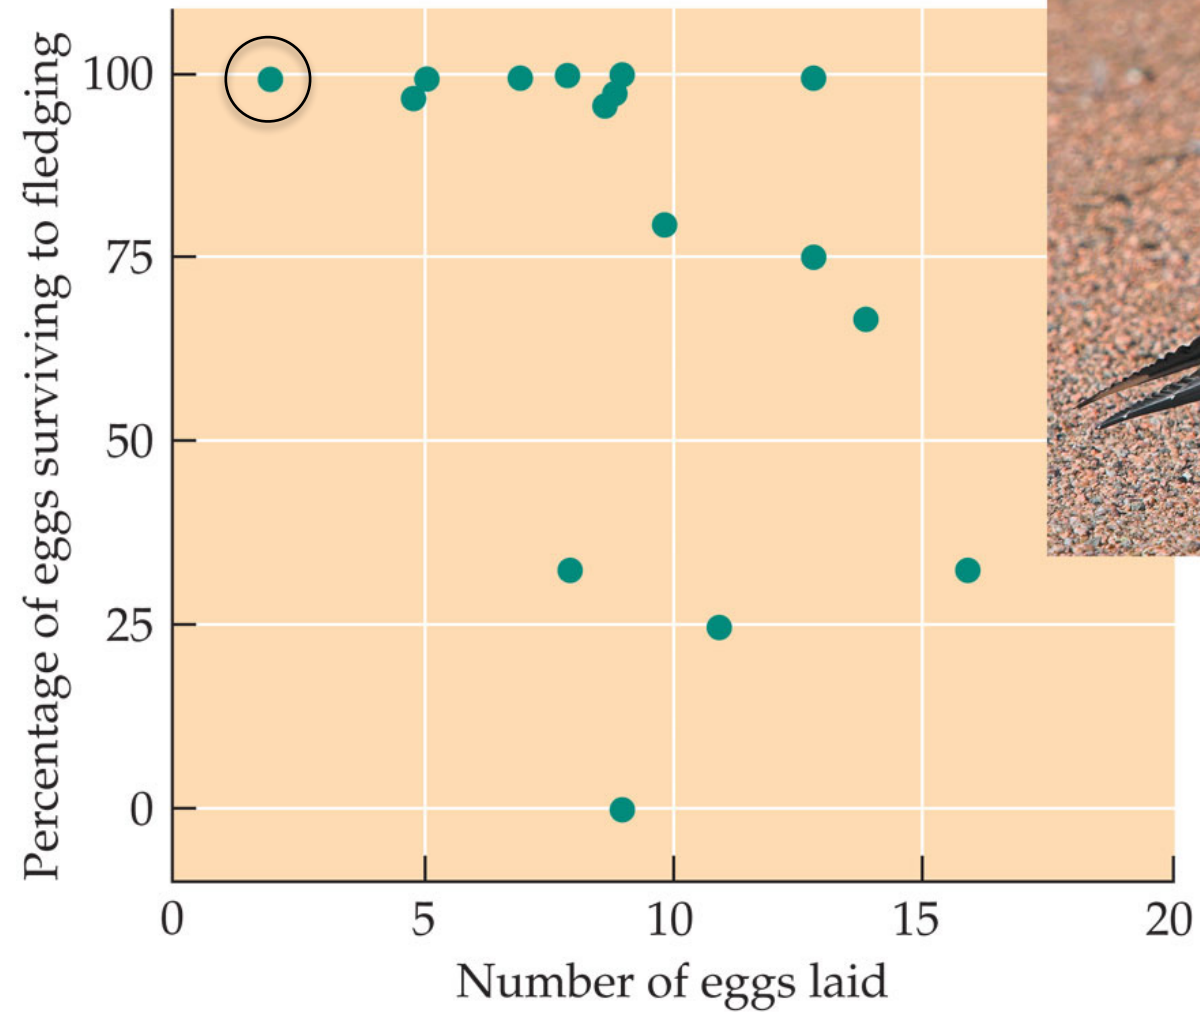

$\gamma \sim$ prob. of mortality ~~with~~ within a time bin

$p_0 \sim$ mortality of offspring

$$\Phi = (1-\gamma)(1-\gamma)(1-\gamma)(1-\gamma)(1-\gamma)(1-\gamma)$$

$$= (1-\gamma)^6 \times 200 \times (1-p_0)$$

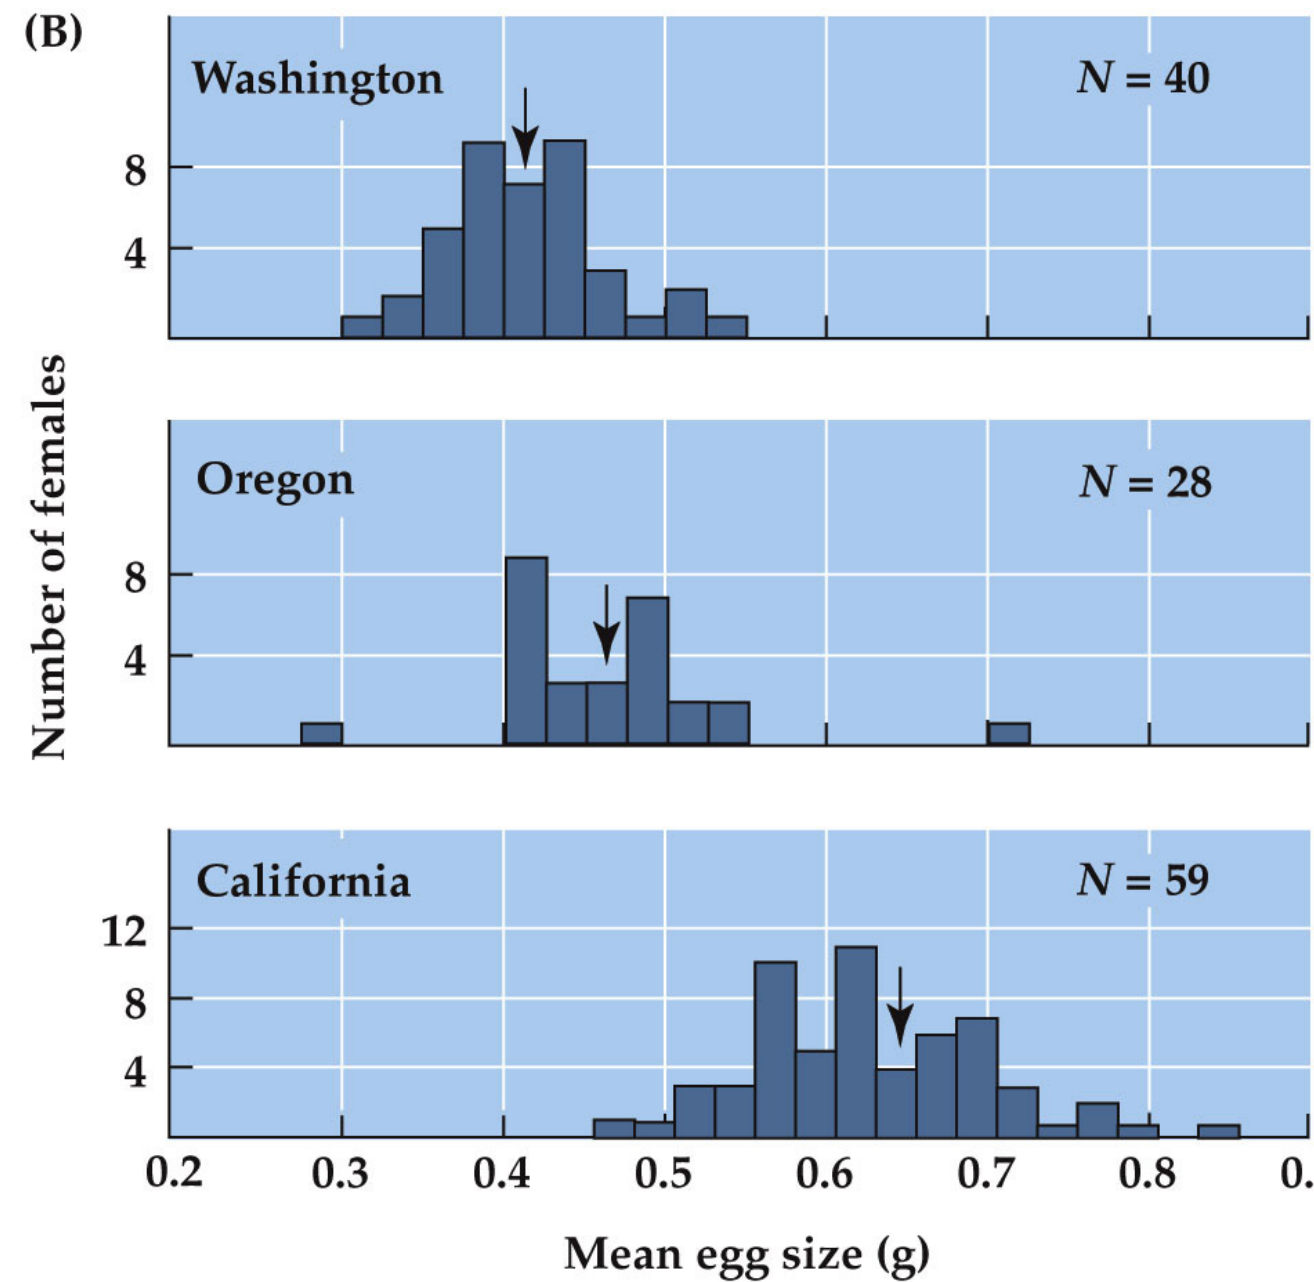

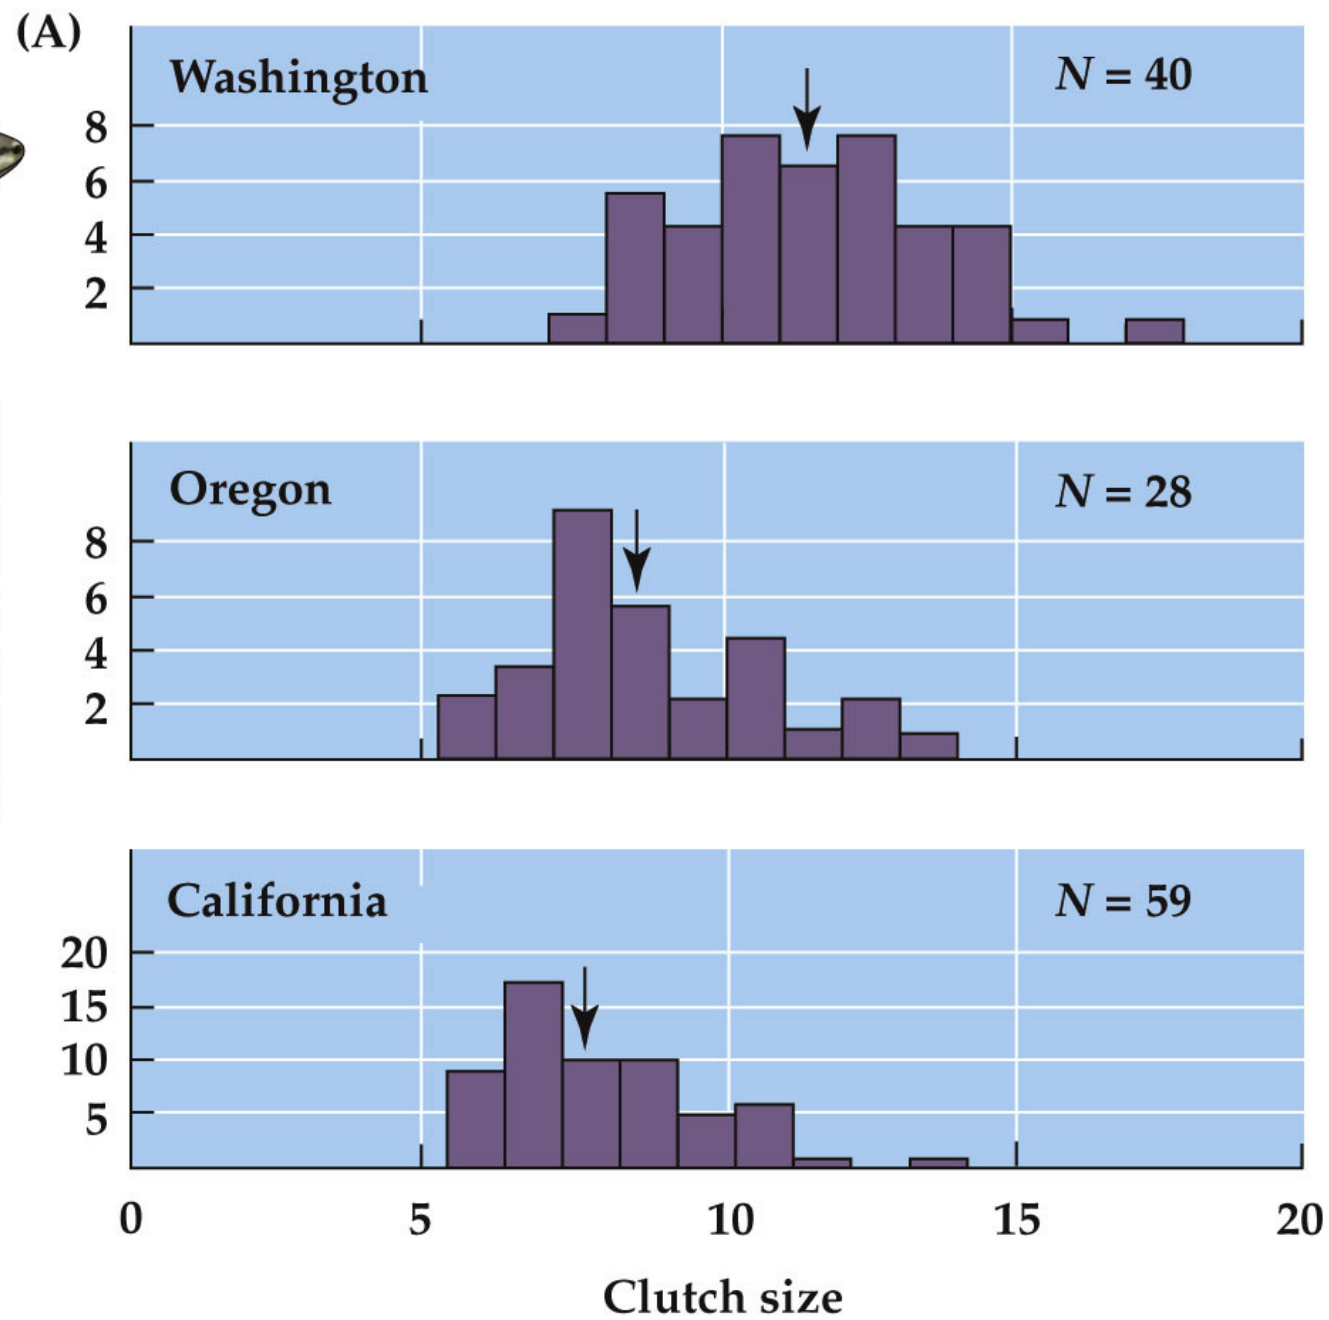

Trade offs!

Larus fuscus

Number of females
